

FEATURES

- 2 selectable differential inputs
- Selectable LVDS/CMOS outputs
- Up to 12 LVDS (1.2 GHz) or 24 CMOS (250 MHz) outputs
- <12 mW per channel (100 MHz operation)
- 54 fs rms integrated jitter (12 kHz to 20 MHz)
- 100 fs rms additive broadband jitter
- 2.0 ns propagation delay (LVDS)
- 135 ps output rise/fall (LVDS)
- 70 ps output-to-output skew (LVDS)
- Sleep mode
- Pin programmable control
- 1.8 V power supply

APPLICATIONS

- Low jitter clock distribution
- Clock and data signal restoration
- Level translation
- Wireless communications
- Wired communications
- Medical and industrial imaging
- ATE and high performance instrumentation

GENERAL DESCRIPTION

The ADCLK854 is a 1.2 GHz/250 MHz LVDS/CMOS fanout buffer optimized for low jitter and low power operation. Possible configurations range from 12 LVDS to 24 CMOS outputs, including combinations of LVDS and CMOS outputs. Three control lines are used to determine whether fixed blocks of outputs (three banks of four) are LVDS or CMOS outputs.

The ADCLK854 offers two selectable inputs and a sleep mode feature. The IN_SEL pin state determines which input is fanned out to all the outputs. The SLEEP pin enables a sleep mode to power down the device.

The inputs accept various types of single-ended and differential logic levels including LVPECL, LVDS, HSTL, CML, and CMOS. Table 8 provides interface options for each type of connection.

This device is available in a 48-pin LFCSP package. It is specified for operation over the standard industrial temperature range of -40°C to +85°C.

SPECIFICATIONS

ELECTRICAL CHARACTERISTICS

Typical (Typ) values are given for $V_S = 1.8\text{ V}$ and $T_A = 25^\circ\text{C}$, unless otherwise noted. Minimum (Min) and maximum (Max) values are given over the full $V_S = 1.8\text{ V} \pm 5\%$ and $T_A = -40^\circ\text{C}$ to $+85^\circ\text{C}$ variation, unless otherwise noted. Input slew rate $> 1\text{ V/ns}$, unless otherwise noted.

Table 1. Clock Inputs and Outputs

| Parameter | Symbol | Min | Typ | Max | Unit | Conditions |
|---------------------------------|------------------|---------------|---------|---------------|---------------|--|
| CLOCK INPUTS | | | | | | |
| Input Frequency | | 0 | | 1200 | MHz | Differential input |
| Input Sensitivity, Differential | | | 150 | | mV p-p | Jitter performance improves with higher slew rates (greater voltage swing) |
| Input Level | | | | 1.8 | V p-p | Larger voltage swings can turn on the protection diodes and degrade jitter performance |
| Input Common-Mode Voltage | V_{CM} | $V_S/2 - 0.1$ | | $V_S/2 + 0.5$ | V | Inputs are self-biased; enables ac coupling |
| Input Common-Mode Range | V_{CMR} | 0.4 | | $V_S - 0.4$ | V | Inputs dc-coupled with 200 mV p-p signal applied |
| Input Voltage Offset | | | 30 | | mV | |
| Input Sensitivity, Single-Ended | | | 150 | | mV p-p | CLKx ac-coupled; \overline{CLKx} ac bypassed to ground |
| Input Resistance (Differential) | | | 7 | | k Ω | |
| Input Capacitance | C_{IN} | | 2 | | pF | |
| Input Bias Current (Each Pin) | | -350 | | +350 | μA | Full input swing |
| LVDS CLOCK OUTPUTS | | | | | | |
| Output Frequency | | | | 1200 | MHz | Termination = 100 Ω ; differential (OUTx, \overline{OUTx}) |
| Output Voltage Differential | V_{OD} | 247 | 344 | 454 | mV | See Figure 9 for swing vs. frequency |
| Delta V_{OD} | ΔV_{OD} | | | 50 | mV | |
| Offset Voltage | V_{OS} | 1.125 | 1.25 | 1.375 | V | |
| Delta V_{OS} | ΔV_{OS} | | | 50 | mV | |
| Short-Circuit Current | I_{SA}, I_{SB} | | 3 | 6 | mA | Each pin (output shorted to GND) |
| CMOS CLOCK OUTPUTS | | | | | | |
| Output Frequency | | | | 250 | MHz | Single-ended; termination = open; OUTx and \overline{OUTx} in phase |
| Output Voltage High | V_{OH} | $V_S - 0.1$ | | | V | With 10 pF load per output; see Figure 16 for swing vs. frequency |
| Output Voltage Low | V_{OL} | | | 0.1 | V | @ 1 mA load |
| Output Voltage High | V_{OH} | $V_S - 0.35$ | | | V | @ 10 mA load |
| Output Voltage Low | V_{OL} | | | 0.35 | V | @ 10 mA load |
| Reference Voltage | V_{REF} | | | | | |
| Output Voltage | | $V_S/2 - 0.1$ | $V_S/2$ | $V_S/2 + 0.1$ | V | $\pm 500\ \mu\text{A}$ |
| Output Resistance | | | 60 | | Ω | |
| Output Current | | | | 500 | μA | |

| SLEEP | | | | 3 | mA | SLEEP pin pulled high; does not include power dissipated in the external resistors |
| Power Supply Rejection ² | | | | | | |
| LVDS | PSR _{t_{PD}} | | 0.9 | | ps/mV | |
| CMOS | PSR _{t_{PD}} | | 1.2 | | ps/mV | |

¹ These pins each have a 200 kΩ internal pull-down resistor.

² Change in t_{PD} per change in V_S.

ABSOLUTE MAXIMUM RATINGS

Table 5.

| Parameter | Rating |
|---|----------------------------------|
| Supply Voltage V _S to GND | 2 V |
| Inputs CLKx and $\overline{\text{CLKx}}$ CMOS Inputs | -0.3 V to +2 V -0.3 V to +2 V |
| Outputs Maximum Voltage Voltage Reference Voltage (V _{REF}) | -0.3 V to +2 V -0.3 to +2 V |
| Operating Temperature Ambient Range Junction | -40°C to +85°C 150°C |
| Storage Temperature Range | -65°C to +150°C |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

DETERMINING JUNCTION TEMPERATURE

To determine the junction temperature on the application printed circuit board (PCB), use the following equation:

$$T_J = T_{CASE} + (\Psi_{JT} \times P_D)$$

where:

T_J is the junction temperature (°C).

T_{CASE} is the case temperature (°C) measured by the user at the top center of the package.

Ψ_{JT} is from Table 6.

P_D is the power dissipation.

Values of θ_{JA} are provided for package comparison and PCB design considerations. θ_{JA} can be used for a first-order approximation of T_J by the equation

$$T_J = T_A + (\theta_{JA} \times P_D)$$

where T_A is the ambient temperature (°C).

Values of θ_{JB} are provided in Table 6 for package comparison and PCB design considerations.

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THERMAL PERFORMANCE

Table 6.

| Parameter | Symbol | Description (Using a 2S2P Test Board) | Value ¹ | Unit |
|--|----------------|---------------------------------------|--------------------|--------------|
| Junction-to-Ambient Thermal Resistance Still Air 0.0 m/sec Air Flow | θ_{JA} | Per JEDEC JESD51-2 | 42 | °C/W |
| Moving Air 1.0 m/sec Air Flow 2.5 m/sec Air Flow | θ_{JMA} | Per JEDEC JESD51-6 | 37 33 | °C/W °C/W |
| Junction-to-Board Thermal Resistance Moving Air 1.0 m/sec Air Flow | θ_{JB} | Per JEDEC JESD51-8 | 26 | °C/W |
| Junction-to-Case Thermal Resistance Moving Air Die-to-Heat Sink | θ_{JC} | Per MIL-STD 883, Method 1012.1 | 2 | °C/W |
| Junction-to-Top-of-Package Characterization Parameter Still Air 0 m/sec Air Flow | Ψ_{JT} | Per JEDEC JESD51-2 | 0.5 | °C/W |

¹ Results are from simulations. The PCB is a JEDEC multilayer type. Thermal performance for actual applications requires careful inspection of the conditions in the application to determine if they are similar to those assumed in these calculations.

PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

ADCLK854

FUNCTIONAL DESCRIPTION

The ADCLK854 accepts a clock input from one of two inputs and distributes the selected clock to all output channels. The outputs are grouped into three banks of four and can be set to either LVDS or CMOS levels. This allows the selection of multiple logic configurations ranging from 12 LVDS to 24 CMOS outputs, along with other combinations using both types of logic.

CLOCK INPUTS

The ADCLK854 differential inputs are internally self-biased. The clock inputs have a resistor divider that sets the common-mode level for the inputs. The complementary inputs are biased about 30 mV lower than the true input to avoid oscillations if the input signal stops. See Figure 20 for the equivalent input circuit.

The inputs can be ac-coupled or dc-coupled. Table 8 displays a guide for input logic compatibility. A single-ended input can be accommodated by ac or dc coupling to one side of the differential input; bypass the other input to ground with a capacitor.

Note that jitter performance degrades with low input slew rate, as shown in Figure 11. See Figure 27 through Figure 32 for different termination schemes.

Figure 20. ADCLK854 Input Stage

AC-COUPLED INPUT APPLICATIONS

The ADCLK854 offers two options for ac coupling. The first option requires no external components (excluding the dc blocking capacitor), it allows the user to simply couple the reference signal onto the clock input pins. For more information, see Figure 29.

The second option allows the use of the V_{REF} pin to set the dc bias level for the ADCLK854. The V_{REF} pin can be connected to $CLKx$ and $CLKx$ through resistors. This method allows lower impedance termination of signals at the ADCLK854 (for more information, see Figure 32). The internal bias resistors remain in parallel with the external biasing. However, the relatively high impedance of the internal resistors allows the external termination to V_{REF} to dominate. This method is also useful when offsetting the inputs; using only the internal biasing, as previously mentioned, is not desirable.

CLOCK OUTPUTS

Each driver consists of a differential LVDS output or two single-ended CMOS outputs (always in phase). When the LVDS driver is enabled, the corresponding CMOS driver is in tristate; when the CMOS driver is enabled, the corresponding LVDS driver is powered down and tristated. Figure 21 and Figure 22 display the equivalent output stage.

Figure 21. LVDS Output Simplified Equivalent Circuit

Figure 22. CMOS Output Equivalent Circuit

Table 8. Input Logic Compatibility

| Supply (V) | Logic | Common Mode (V) | Output Swing (V) | AC-Coupled | DC-Coupled |
|------------|--------|-----------------|------------------|-------------|-------------|
| 3.3 | CML | 2.9 | 0.8 | Yes | Not allowed |
| 2.5 | CML | 2.1 | 0.8 | Yes | Not allowed |
| 1.8 | CML | 1.4 | 0.8 | Yes | Yes |
| 3.3 | CMOS | 1.65 | 3.3 | Not allowed | Not allowed |
| 2.5 | CMOS | 1.25 | 2.5 | Not allowed | Not allowed |
| 1.8 | CMOS | 0.9 | 1.8 | Yes | Yes |
| 1.5 | HSTL | 0.75 | 0.75 | Yes | Yes |
| | LVDS | 1.25 | 0.4 | Yes | Yes |
| 3.3 | LVPECL | 2.0 | 0.8 | Yes | Not allowed |
| 2.5 | LVPECL | 1.2 | 0.8 | Yes | Yes |
| 1.8 | LVPECL | 0.5 | 0.8 | Yes | Yes |

CONTROL AND FUNCTION PINS

CTRL_A—Logic Select

This pin selects either CMOS (high) or LVDS (low) logic for Output 3, Output 2, Output 1, and Output 0. This pin has an internal 200 k Ω pull-down resistor.

CTRL_B—Logic Select

This pin selects either CMOS (high) or LVDS (low) logic for Output 7, Output 6, Output 5, and Output 4. This pin has an internal 200 k Ω pull-down resistor.

CTRL_C—Logic Select

This pin selects either CMOS (high) or LVDS (low) logic for Output 11, Output 10, Output 9, and Output 8. This pin has an internal 200 k Ω pull-down resistor.

IN_SEL—Clock Input Select

A logic low selects CLK0 and $\overline{\text{CLK0}}$ whereas a logic high selects CLK1 and $\overline{\text{CLK1}}$. This pin has an internal 200 k Ω pull-down resistor.

Sleep Mode

Sleep mode powers down the chip except for the internal band gap. The input is active high, which puts the outputs into a high-Z state. This pin has a 200 k Ω pull-down resistor.

POWER SUPPLY

The ADCLK854 requires a 1.8 V \pm 5% power supply for V_s . Best practice recommends bypassing the power supply on the PCB

with adequate capacitance ($>10 \mu\text{F}$), and bypassing all power pins with adequate capacitance (0.1 μF) as close to the part as possible. The layout of the ADCLK854 evaluation board (ADCLK854/PCBZ) provides a good layout example.

Exposed Metal Paddle

The exposed metal paddle on the ADCLK854 package is an electrical connection as well as a thermal enhancement. For the device to function properly, the paddle must be properly attached to ground (GND). The ADCLK854 dissipates heat through its exposed paddle. The PCB acts as a heat sink for the ADCLK854. The PCB attachment must provide a good thermal path to a larger heat dissipation area, such as the ground plane on the PCB. This requires a grid of vias from the top layer down to the ground plane. See Figure 23 for an example.

APPLICATIONS INFORMATION

USING THE ADCLK854 OUTPUTS FOR ADC CLOCK APPLICATIONS

Any high speed, analog-to-digital converter (ADC) is extremely sensitive to the quality of the sampling clock provided by the user. An ADC can be thought of as a sampling mixer, and any noise, distortion, or timing jitter on the clock is combined with the desired signal at the analog-to-digital output. Clock integrity requirements scale with the analog input frequency and resolution, with higher analog input frequency applications at ≥ 14 -bit resolution being the most stringent. The theoretical SNR of an ADC is limited by the ADC resolution and the jitter on the sampling clock. Considering an ideal ADC of infinite resolution where the step size and quantization error can be ignored, the available SNR can be expressed approximately by

$$SNR = 20 \times \log \left[\frac{1}{2\pi f_A T_J} \right]$$

where f_A is the highest analog frequency being digitized and T_J is the rms jitter on the sampling clock.

Figure 24 shows the required sampling clock jitter as a function of the analog frequency and effective number of bits (ENOB). For more information, see Application Note AN-756 and Application Note AN-501 at www.analog.com.

Figure 24. SNR and ENOB vs. Analog Input Frequency

Many high performance ADCs feature differential clock inputs to simplify the task of providing the required low jitter clock on a noisy PCB. Distributing a single-ended clock on a noisy PCB can result in coupled noise on the sample clock. Differential distribution has inherent common-mode rejection that can provide superior clock performance in a noisy environment. Consider the input requirements of the ADC (differential or single-ended, logic level, and termination) when selecting the best clocking/converter solution.

LVDS CLOCK DISTRIBUTION

The ADCLK854 provides clock outputs that are selectable as either CMOS or LVDS level outputs. LVDS is a differential output option that uses a current-mode output stage. The nominal current is 3.5 mA, which yields 350 mV output swing across a 100 Ω resistor. The LVDS output meets or exceeds all ANSI/TIA/EIA-644 specifications. A recommended termination circuit for the LVDS outputs is shown in Figure 25.

If ac coupling is necessary, place decoupling capacitors either before or after the 100 Ω termination resistor. See Application Note AN-586 at www.analog.com for more information on LVDS.

Figure 25. LVDS Output Termination

CMOS CLOCK DISTRIBUTION

The output drivers of the ADCLK854 can be configured as CMOS drivers. When selected as a CMOS driver, each output becomes a pair of CMOS outputs. These outputs are 1.8 V CMOS compatible.

When single-ended CMOS clocking is used, some of the following guidelines apply.

Design point-to-point connections such that each driver has only one receiver, if possible. Connecting outputs in this manner allows for simple termination schemes and minimizes ringing due to possible mismatched impedances on the output trace. Series termination at the source is generally required to provide transmission line matching and/or to reduce current transients at the driver.

The value of the resistor (typically 10 Ω to 100 Ω) is dependent on the board design and timing requirements. CMOS outputs are also limited in terms of the capacitive load or trace length that they can drive. Typically, trace lengths less than 3 inches are recommended to preserve signal rise/fall times and signal integrity.

Figure 26. Series Termination of CMOS Output

Termination at the far end of the PCB trace is a second option. The CMOS outputs of the ADCLK854 do not supply enough current to provide a full voltage swing with a low impedance resistive, far end termination, as shown in Figure 27. The far end termination network should match the PCB trace impedance and provide the desired switching point. The reduced signal swing may

still meet receiver input requirements in some applications. This can be useful when driving long trace lengths on less critical networks.

Figure 27. CMOS Output with Far End Termination

Because of the limitations of single-ended CMOS clocking, consider using differential outputs when driving high speed signals over long traces. The ADCLK854 offers LVDS outputs that are better suited for driving long traces wherein the inherent noise immunity of differential signaling provides superior performance for clocking converters.

INPUT TERMINATION OPTIONS

For single-ended operation always bypass unused input to GND, as shown in Figure 31.

Figure 32 illustrates the use of VREF to provide low impedance termination into Vs/2. In addition, a way to negate the 30 mV input offset is with external resistor values; for example, using a 1.8 V CMOS with long traces to provide far end termination.
